## HIGHLIGHTS OF PRESCRIBING INFORMATION

These highlights do not include all the information needed to use DICLOFENAC POTASSIUM FOR ORAL SOLUTION safely and effectively. See full prescribing information for DICLOFENAC POTASSIUM FOR ORAL SOLUTION.

DICLOFENAC POTASSIUM for oral solution  
Initial U.S. Approval: 1988

### WARNING: RISK OF SERIOUS CARDIOVASCULAR AND GASTROINTESTINAL EVENTS

See full prescribing information for complete boxed warning

- Non-steroidal anti-inflammatory drugs (NSAIDs) cause an increased risk of serious cardiovascular thrombotic events, including myocardial infarction and stroke, which can be fatal. This risk may occur early in treatment and may increase with duration of use (5.1)
- Diclofenac potassium for oral solution is contraindicated in the setting of coronary artery bypass graft (CABG) surgery (4, 5.1)
- NSAIDs cause an increased risk of serious gastrointestinal (GI) adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. These events can occur at any time during use and without warning symptoms. Elderly patients and patients with a prior history of peptic ulcer disease and/or GI bleeding are at greater risk for serious GI events (5.2)

### INDICATIONS AND USAGE

Diclofenac potassium for oral solution is a non-steroidal anti-inflammatory drug (NSAID) indicated for the acute treatment of migraine attacks with or without aura in adults 18 years of age or older (1)

#### Limitations of Use (1):

- Diclofenac potassium for oral solution is not indicated for the prophylactic therapy of migraine
- Safety and effectiveness of diclofenac potassium for oral solution not established for cluster headache, which is present in an older, predominantly male population

### DOSEAGE AND ADMINISTRATION

Single 50 mg dose; mix single packet contents with 1 to 2 ounces or 2 to 4 tablespoons (30 to 60 mL) of water prior to administration

- Use the lowest effective dose for shortest duration consistent with individual patient treatment goals (2.1)

### DOSEAGE FORMS AND STRENGTHS

Packets: Each containing buffered diclofenac potassium 50 mg in a soluble powder (3)

### CONTRAINDICATIONS

- Known hypersensitivity to diclofenac or NSAIDs or any components of the drug product (4)
- History of asthma, urticaria, or other allergic-type reactions after taking aspirin or other NSAIDs (4)
- In the setting of (CABG) surgery (4)

### WARNINGS AND PRECAUTIONS

- Hepatotoxicity: Discontinue if abnormal liver tests persist or worsen or if clinical signs and symptoms of liver disease develop (5.3, 8.6, 12.3)
- Hypertension: Patients taking some antihypertensive medications may have impaired response to these therapies when taking NSAIDs. Monitor blood pressure (5.4, 7)

## FULL PRESCRIBING INFORMATION

### WARNING: RISK OF SERIOUS CARDIOVASCULAR AND GASTROINTESTINAL EVENTS

- Cardiovascular Thrombotic Events**
  - Nonsteroidal anti-inflammatory drugs (NSAIDs) cause an increased risk of serious cardiovascular thrombotic events, including myocardial infarction and stroke, which can be fatal. This risk may occur early in treatment and may increase with duration of use [see Warnings and Precautions (5.1)].
- Diclofenac potassium for oral solution is contraindicated in the setting of coronary artery bypass graft (CABG) surgery [see Contraindications (4) and Warnings and Precautions (5.1)].**
- Gastrointestinal Bleeding, Ulceration, and Perforation**
  - NSAIDs cause an increased risk of serious gastrointestinal (GI) adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. These events can occur at any time during use and without warning symptoms. Elderly patients and patients with a prior history of peptic ulcer disease and/or GI bleeding are at greater risk for serious GI events [see Warnings and Precautions (5.2)].

### INDICATIONS AND USAGE

Diclofenac potassium for oral solution is indicated for the acute treatment of migraine attacks with or without aura in adults (18 years of age or older).

#### Limitations of Use

- Diclofenac potassium for oral solution is not indicated for the prophylactic therapy of migraine.
- The safety and effectiveness of diclofenac potassium for oral solution have not been established for cluster headache, which is present in an older, predominantly male population.

### DOSEAGE AND ADMINISTRATION

#### 2.1 Acute Treatment of Migraine

Administer one packet (50 mg) of diclofenac potassium for oral solution for the acute treatment of migraine. Empty the contents of one packet into a cup containing 1 to 2 ounces (30 mL) of water, mix well and drink immediately. Do not use liquids other than water. Taking diclofenac potassium for oral solution with food may cause a reduction in effectiveness compared to taking diclofenac potassium for oral solution on an empty stomach [see Clinical Pharmacology (12.3)].

Use the lowest effective dose for the shortest duration consistent with individual patient treatment goals. The safety and effectiveness of a second dose have not been established.

#### 2.2 Non-Interchangeability with Other Formulations of Diclofenac

Different formulations of oral diclofenac (i.e., diclofenac potassium for oral solution, diclofenac sodium enteric-coated tablets, diclofenac sodium extended-release tablets, or diclofenac potassium immediate-release tablets) may not be bioequivalent if the milligram strength is the same. Therefore, it is not possible to convert dosing from any other formulation of diclofenac to diclofenac potassium for oral solution.

### DOSEAGE FORMS AND STRENGTHS

Diclofenac potassium for oral solution, USP is available in individual packets each designed to deliver a 50 mg dose when mixed in water.

### CONTRAINDICATIONS

Diclofenac potassium for oral solution is contraindicated in the following patients:

- Known hypersensitivity (e.g., anaphylactic reactions and serious skin reactions) to diclofenac or any components of the drug product [see Warnings and Precautions (5.7, 5.9)]
- History of asthma, urticaria, or other allergic-type reactions after taking aspirin or other NSAIDs. Severe, sometimes fatal, anaphylactic reactions to NSAIDs have been reported in such patients [see Warnings and Precautions (5.7, 5.8)]
- In the setting of coronary artery bypass graft (CABG) surgery [see Warnings and Precautions (5.1)]

### WARNINGS AND PRECAUTIONS

#### 5.1 Cardiovascular Thrombotic Events

Clinical trials of several COX-2 selective and nonselective NSAIDs of up to three years duration have shown an increased risk of serious cardiovascular (CV) thrombotic events, including myocardial infarction (MI) and stroke, which can be fatal on available data. It is unclear that the risk for CV thrombotic events is similar for all NSAIDs. The relative increase in serious CV thrombotic events over baseline conferred by NSAID use appears to be similar in those with and without known CV disease or risk factors for CV disease. However, patients with known CV disease or risk factors had a higher absolute incidence of excess serious CV thrombotic events due to their increased baseline rate. Some observational studies found that this increased risk of serious CV thrombotic events began as early as the first weeks of treatment. The increase in CV thrombotic risk has been observed most consistently at higher doses. To minimize the potential risk for an adverse CV event in NSAID-treated patients, use the lowest effective dose for the shortest duration possible. Physicians and patients should remain alert for the development of such events, throughout the entire treatment course, even in the absence of previous CV symptoms. Patients should be informed about the symptoms of serious CV events and the steps to take if they occur. There is no consistent evidence that concurrent use of aspirin mitigates the increased risk of serious CV thrombotic events associated with NSAID use. The concurrent use of aspirin and an NSAID, such as diclofenac, increases the risk of serious gastrointestinal (GI) events [see Warnings and Precautions (5.2)].

Status Post Coronary Artery Bypass Graft (CABG) Surgery.

Two large, controlled clinical trials of a COX-2 selective NSAID for the treatment of pain in the first 10 to 14 days following CABG surgery found an increased incidence of myocardial infarction and stroke. NSAIDs are contraindicated in the setting of CABG [see Contraindications (4)].

#### 5.2 Gastrointestinal Bleeding, Ulceration, and Perforation

Clinical trials of several COX-2 selective and nonselective NSAIDs of up to three years duration have shown an increased risk of serious cardiovascular (CV) thrombotic events, including myocardial infarction (MI) and stroke, which can be fatal. These serious adverse events can occur at any time, with or without warning symptoms, in patients treated with NSAIDs. Only one in five patients who develop a serious upper GI adverse event on NSAID therapy is symptomatic. Upper GI ulcers, gross bleeding, or perforation caused by NSAIDs occurred in approximately 1% of patients treated for 3 to 6 months, and in about 2% in 4% of patients treated for one year. However, even short-term NSAID therapy is not without risk.

Risk Factors for GI Bleeding, Ulceration, and Perforation.

Patients with a prior history of peptic ulcer disease and/or GI bleeding who used NSAIDs had a greater than 10-fold increased risk for developing a GI bleed compared to patients without these risk factors. Other factors that increase the risk for GI bleeding in patients treated with NSAIDs include longer duration of NSAID therapy; concomitant use of oral corticosteroids, aspirin, anticoagulants, or selective serotonin reuptake inhibitors (SSRIs); smoking; use of alcohol; older age; and poor general health status. Most postmarketing reports of fatal GI events occurred in elderly or debilitated patients. Additionally, patients with advanced liver disease and/or coagulopathy are at increased risk for GI bleeding.

Strategies to Minimize the GI Risk in NSAID-Treated Patients:

- Use the lowest effective dose for the shortest possible duration.
- Avoid administration of more than one NSAID at a time.
- Avoid use in patients at higher risk unless benefits are expected to outweigh the increased risk of bleeding. For high risk patients, as well as those with active GI bleeding, consider alternate therapies other than NSAIDs.
- Remain alert for signs and symptoms of GI ulceration and bleeding during NSAID therapy.
- If a serious GI adverse event is suspected, promptly initiate evaluation and treatment, and discontinue diclofenac potassium for oral solution until a serious GI adverse event is ruled out.
- In the setting of concomitant use of low-dose aspirin for cardiac prophylaxis, monitor patients more closely for evidence of GI bleeding [see Drug Interactions (7)].

#### 5.3 Hepatotoxicity

Elevations of one or more liver tests may occur during therapy with diclofenac potassium for oral solution. These laboratory abnormalities are usually asymptomatic and transient. The normal effects with continued therapy. Borderline elevations (less than 3 times the upper limit of the normal ULN) range or greater elevations of transaminases occurred in about 15% of diclofenac-treated patients. GI the markers of liver function. ALT (SGPT) is recommended for the monitoring of liver injury.

In clinical trials, meaningful elevations (i.e., more than 3 times the ULN of AST (SGOT) occurred in about 2% of approximately 5,700 patients at some time during treatment. ALT was not measured in all studies. In an open-label, controlled trial of 3,700 patients treated for 2 to 6 months, patients were monitored at 8 weeks and 1,200 patients were monitored again at 24 weeks. Meaningful elevations of ALT and/or AST occurred in about 4% of the 3,700 patients and included marked elevations ( $\geq 8$  times the ULN) in about 1% of the 3,700 patients. In this open-label study, a higher incidence of borderline (less than 3 times the ULN), moderate (3 to 8 times the ULN), and marked ( $\geq 8$  times the ULN) elevations of ALT or AST was observed in patients receiving diclofenac when compared to other NSAIDs. However, almost all meaningful elevations in transaminases were detected before patients became symptomatic [see Warnings and Precautions (5.15)].

Abnormal tests occurred during the first 2 months of therapy with diclofenac in 42 of the 51 patients in all trials who developed marked transaminase elevations. In postmarketing reports, cases of drug-induced hepatotoxicity have been reported in the first month, and in some cases, the first 2 months of NSAID therapy. In an open-label, controlled trial of 3,700 patients treated for 2 to 6 months, patients were monitored at 8 weeks and 1,200 patients were monitored again at 24 weeks. Meaningful elevations of ALT and/or AST occurred in about 4% of the 3,700 patients and included marked elevations ( $\geq 8$  times the ULN) in about 1% of the 3,700 patients. In this open-label study, a higher incidence of borderline (less than 3 times the ULN), moderate (3 to 8 times the ULN), and marked ( $\geq 8$  times the ULN) elevations of ALT or AST was observed in patients receiving diclofenac when compared to other NSAIDs. However, almost all meaningful elevations in transaminases were detected before patients became symptomatic [see Warnings and Precautions (5.15)].

In an open-label, controlled trial of 3,700 patients treated for 2 to 6 months, patients were monitored at 8 weeks and 1,200 patients were monitored again at 24 weeks. Meaningful elevations of ALT and/or AST occurred in about 4% of the 3,700 patients and included marked elevations ( $\geq 8$  times the ULN) in about 1% of the 3,700 patients. In this open-label study, a higher incidence of borderline (less than 3 times the ULN), moderate (3 to 8 times the ULN), and marked ( $\geq 8$  times the ULN) elevations of ALT or AST was observed in patients receiving diclofenac when compared to other NSAIDs. However, almost all meaningful elevations in transaminases were detected before patients became symptomatic [see Warnings and Precautions (5.15)].

Abnormal tests occurred during the first 2 months of therapy with diclofenac in 42 of the 51 patients in all trials who developed marked transaminase elevations. In postmarketing reports, cases of drug-induced hepatotoxicity have been reported in the first month, and in some cases, the first 2 months of NSAID therapy. In an open-label, controlled trial of 3,700 patients treated for 2 to 6 months, patients were monitored at 8 weeks and 1,200 patients were monitored again at 24 weeks. Meaningful elevations of ALT and/or AST occurred in about 4% of the 3,700 patients and included marked elevations ( $\geq 8$  times the ULN) in about 1% of the 3,700 patients. In this open-label study, a higher incidence of borderline (less than 3 times the ULN), moderate (3 to 8 times the ULN), and marked ( $\geq 8$  times the ULN) elevations of ALT or AST was observed in patients receiving diclofenac when compared to other NSAIDs. However, almost all meaningful elevations in transaminases were detected before patients became symptomatic [see Warnings and Precautions (5.15)].

BLACK

840 mm

Digoxin	
<b>Clinical Impact:</b>	The concomitant use of diclofenac with digoxin has been reported to increase the serum concentration and prolong the half-life of digoxin.
<b>Intervention:</b>	During concomitant use of diclofenac potassium for oral solution and digoxin, monitor serum digoxin levels.
Lithium	
<b>Clinical Impact:</b>	NSAIDs have produced elevations in plasma lithium levels and reductions in renal lithium clearance. The mean minimum lithium concentration increased 15%, and the renal clearance decreased by approximately 20%. This effect has been attributed to NSAID inhibition of renal prostaglandin synthesis.
<b>Intervention:</b>	During concomitant use of diclofenac potassium for oral solution and lithium, monitor patients for signs of lithium toxicity.
Methotrexate	
<b>Clinical Impact:</b>	Concomitant use of NSAIDs and methotrexate may increase the risk for methotrexate toxicity (e.g., neutropenia, thrombocytopenia, renal dysfunction).
<b>Intervention:</b>	During concomitant use of diclofenac potassium for oral solution and methotrexate, monitor patients for methotrexate toxicity.
Cyclosporine	
<b>Clinical Impact:</b>	Concomitant use of diclofenac potassium for oral solution and cyclosporine may increase cyclosporine's nephrotoxicity.
<b>Intervention:</b>	During concomitant use of diclofenac potassium for oral solution and cyclosporine, monitor patients for signs of worsening renal function.
NSAIDs and Salicylates	
<b>Clinical Impact:</b>	Concomitant use of diclofenac with other NSAIDs or salicylates (e.g., diflunisal, salsalate) increases the risk of GI toxicity, with little or no increase in efficacy [see <b>Warnings and Precautions (5.2)</b> ].
<b>Intervention:</b>	The concomitant use of diclofenac with other NSAIDs or salicylates is not recommended.
Pemetrexed	
<b>Clinical Impact:</b>	Concomitant use of diclofenac potassium for oral solution and pemetrexed may increase the risk of pemetrexed-associated myelosuppression, renal, and GI toxicity [see the pemetrexed prescribing information].
<b>Intervention:</b>	During concomitant use of NSAIDs and pemetrexed, in patients with renal impairment whose creatinine clearance ranges from 45 to 79 mL/min, monitor for myelosuppression, renal and GI toxicity. NSAIDs with short elimination half-lives (e.g., diclofenac, indomethacin) should be avoided for a period of two days before, the day of, and two days following administration of pemetrexed. In the absence of data regarding potential interaction between pemetrexed and NSAIDs with longer half-lives (e.g., meloxicam, nabumetone), patients taking these NSAIDs should interrupt dosing for at least five days before, the day of, and two days following pemetrexed administration.
Inhibitors of Cytochrome P450 CYP2C9	
<b>Clinical Impact:</b>	Diclofenac is metabolized predominantly by Cytochrome P-450 CYP2C9. Co-administration of medications that inhibit CYP2C9 may affect the pharmacokinetics of diclofenac [see <b>Clinical Pharmacology (12.3)</b> ].
<b>Intervention:</b>	During concomitant use of diclofenac potassium for oral solution and drugs that inhibit CYP2C9, an increase in the duration between diclofenac potassium for oral solution doses for subsequent migraine attacks may be necessary.

9 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary

Use of NSAIDs, including diclofenac potassium for oral solution, can cause premature closure of the fetal ductus arteriosus and fetal renal dysfunction leading to oligohydramnios and, in some cases, neonatal renal impairment. Because of these risks, limit dose and duration of diclofenac potassium for oral solution use between about 20 and 30 weeks of gestation, and avoid diclofenac potassium for oral solution use at about 30 weeks of gestation and later in pregnancy [see **Clinical Considerations, Data**].

Premature Closure of Fetal Ductus Arteriosus

Use of NSAIDs, including diclofenac potassium for oral solution, at about 30 weeks gestation or later in pregnancy increases the risk of premature closure of the fetal ductus arteriosus.

Oligohydramnios/Neonatal Renal Impairment

Use of NSAIDs at about 20 weeks gestation or later in pregnancy has been associated with cases of fetal renal dysfunction leading to oligohydramnios, and in some cases, neonatal renal impairment.

Data from observational studies regarding other potential embryofetal risks of NSAID use in women in the first or second trimesters of pregnancy are inconclusive. In animal studies, oral administration of diclofenac sodium to pregnant mice, rats, and rabbits resulted in adverse effects on development (embryofetal mortality, reduced fetal growth) at doses similar to those used clinically. Based on animal data, prostaglandins have been shown to have an important role in endometrial vascular permeability, blastocyst implantation, and decidualization. In animal studies, administration of prostaglandin synthase inhibitors such as diclofenac potassium, resulted in increased pre- and post-implantation loss. Prostaglandins also have been shown to have an important role in fetal kidney development. In published animal studies, prostaglandin synthase inhibitors have been reported to impair kidney development when administered at clinically relevant doses.

All pregnancies have a background risk of birth defects, loss, or other adverse outcomes. In the U.S. general population, the estimated background risk of major birth defects and miscarriage in clinically recognized pregnancies is 2 to 4% and 15 to 20%, respectively. The reported rate of major birth defects among deliveries to women with migraine ranged from 2.2% to 2.9% and the reported rate of miscarriage was 17%, which were similar to rates reported in women without migraine.

Clinical Considerations

Disease-Associated Maternal and/or Embryo/Fetal Risk

Several studies have suggested that women with migraine may be at increased risk of preeclampsia and gestational hypertension during pregnancy.

Fetal/Neonatal Adverse Reactions

Premature Closure of Fetal Ductus Arteriosus:

Avoid use of NSAIDs in women at about 30 weeks gestation and later in pregnancy, because NSAIDs, including diclofenac potassium for oral solution, can cause premature closure of the fetal ductus arteriosus [see **Data**].

Oligohydramnios/Neonatal Renal Impairment:

If an NSAID is necessary at about 20 weeks gestation or later in pregnancy, limit the use to the lowest effective dose and shortest duration possible. If diclofenac potassium for oral solution treatment extends beyond 48 hours, consider monitoring with ultrasound for oligohydramnios. If oligohydramnios occurs, discontinue diclofenac potassium for oral solution and follow up according to clinical practice [see **Data**].

Labor or Delivery

The effects of diclofenac potassium for oral solution on labor and delivery in pregnant women are unknown. In rat studies, maternal exposure to NSAIDs, as with other drugs known to inhibit prostaglandin synthesis, increased the incidence of dystocia, delayed parturition, and decreased pup survival.

Data

Human Data

Premature Closure of Fetal Ductus Arteriosus:

Published literature reports that the use of NSAIDs at about 30 weeks of gestation and later in pregnancy may cause premature closure of the fetal ductus arteriosus.

Oligohydramnios/Neonatal Renal Impairment:

Published studies and postmarketing reports describe maternal NSAID use at about 20 weeks gestation or later in pregnancy associated with fetal renal dysfunction leading to oligohydramnios, and in some cases, neonatal renal impairment. These adverse outcomes are seen, on average, after days to weeks of treatment, although oligohydramnios has been infrequently reported as soon as 48 hours after NSAID initiation. In many cases, but not all, the decrease in amniotic fluid was transient and reversible with cessation of the drug. There have been a limited number of case reports of maternal NSAID use and neonatal renal dysfunction without oligohydramnios, some of which were irreversible. Some cases of neonatal renal dysfunction required treatment with invasive procedures, such as exchange transfusion or dialysis.

Methodological limitations of these postmarketing studies and reports include lack of a control group; limited information regarding dose, duration, and timing of drug exposure; and concomitant use of other medications. These limitations preclude establishing a reliable estimate of the risk of adverse fetal and neonatal outcomes with maternal NSAID use. Because the published safety data on neonatal outcomes involved mostly preterm infants, the generalizability of certain reported risks to the full-term infant exposed to NSAIDs through maternal use is uncertain.

Animal Data

Oral administration of diclofenac sodium to pregnant mice and rabbits during organogenesis resulted in embryofetal toxicity at oral doses of up to 20 and 10 mg/kg/day (up to approximately 2 and 4 times, respectively, the recommended human dose [RHD] of 50 mg/kg, based on body surface area [mg/m<sup>2</sup>]). In rats, oral administration of diclofenac sodium at doses of up to 10 mg/kg/day (up to approximately 2 times the RHD on a mg/m<sup>2</sup> basis) during organogenesis resulted in increased embryofetal mortality and reduced fetal body weights.

8.2 Lactation

Risk Summary

Data from published literature reports with oral preparations of diclofenac indicate the presence of small amounts of diclofenac in human milk. There are no data on the effects on the breastfed infant, or the effects on milk production. The developmental and health benefits of breastfeeding should be considered along with the mother's clinical need for diclofenac potassium for oral solution and any potential adverse effects on the breastfed infant from diclofenac potassium for oral solution or from the underlying maternal condition.

8.3 Females and Males of Reproductive Potential

Infertility

Females

Based on the mechanism of action, the use of prostaglandin-mediated NSAIDs, including diclofenac potassium for oral solution, may delay or prevent rupture of ovarian follicles, which has been associated with reversible infertility in some women. Published animal studies have shown that administration of prostaglandin synthase inhibitors has the potential to disrupt prostaglandin-mediated follicular rupture required for ovulation. Small studies in women treated with NSAIDs have also shown a reversible delay in ovulation. Consider withdrawal of NSAIDs, including diclofenac potassium for oral solution, in women who have difficulties conceiving or who are undergoing investigation of infertility.

8.4 Pediatric Use

8.5 Geriatric Use

Safety and effectiveness in pediatric patients have not been established.

8.6 Hepatic Impairment

Because hepatic metabolism accounts for almost 100% of diclofenac elimination, patients with hepatic impairment should be considered for treatment with diclofenac potassium for oral solution only if the benefits outweigh the risks. There is insufficient information available to support dosing recommendations for diclofenac potassium for oral solution in patients with hepatic insufficiency [see **Clinical Pharmacology (12.3)**].

8.7 Renal Impairment

No information is available from controlled clinical studies regarding the use of diclofenac potassium for oral solution in patients with advanced renal disease. Therefore, treatment with diclofenac potassium for oral solution is not recommended in patients with advanced renal disease. If diclofenac potassium for oral solution therapy must be initiated, close monitoring of the patient's renal function is advisable.

10 OVERDOSAGE

Symptoms following acute NSAID overdoses have been typically limited to lethargy, drowsiness, nausea, vomiting, and epigastric pain, which have been generally reversible with supportive care. Gastrointestinal bleeding has occurred. Hypertension, acute renal failure, respiratory depression and coma have occurred, but were rare [see **Warnings and Precautions (5.1, 5.2, 5.4, 5.6)**].

Manage patients with symptomatic and supportive care following an NSAID overdose. There are no specific antidotes. Consider emesis and/or activated charcoal (60 to 100 grams in adults, 1 to 2 grams per kg of body weight in pediatric patients) and/or osmotic cathartics in symptomatic patients seen within four hours of ingestion or in patients with a large overdose (5 to 10 times the recommended dose). Forced diuresis, alkalization of urine, hemodialysis, or hemoperfusion may not be useful due to high protein binding.

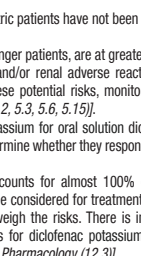

For additional information about overdose treatment contact a poison control center (1-800-222-1222).

Anaphylactic reactions have been reported with therapeutic ingestion of NSAIDs, and may occur following an overdose.

11 DESCRIPTION

Diclofenac potassium for oral solution, USP, is a nonsteroidal anti-inflammatory drug, available as a buffered soluble powder, designed to be mixed with water prior to oral administration. Diclofenac potassium, USP, is a white to off-white, buffered, flavored powder for oral solution packaged in individual unit dose packets.

The chemical name is benzenecacetic acid, 2-[2-(6-chlorophenyl)amino]-, monopotassium salt. The molecular weight is 334.2 g/mol. Its molecular formula is C<sub>16</sub>H<sub>12</sub>Cl<sub>2</sub>NO<sub>2</sub>, and it has the following chemical structure:

The inactive ingredients in diclofenac potassium for oral solution, USP include: aspartame (equivalent to 25 mg phenylalanine), flavoring agent (peppermint), glyceryl dibehenate, mannitol, potassium bicarbonate, and saccharin sodium.

Dispense with Medication Guide available at: [www.taro.com/usa-medication-guides](http://www.taro.com/usa-medication-guides)

Medication Guide Diclofenac Potassium (dyo-KLOE-fen-ak poe-TAS-ee-um) for Oral Solution, USP
<b>What is the most important information I should know about diclofenac potassium for oral solution?</b> Diclofenac potassium for oral solution contains diclofenac (a non-steroidal anti-inflammatory drug or NSAID). <b>NSAIDs, including diclofenac potassium for oral solution, can cause serious side effects, including:</b> <ul style="list-style-type: none"><li>Increased risk of a heart attack or stroke that can lead to death. This risk may happen early in treatment and may increase:<ul style="list-style-type: none"><li>with increasing doses of NSAIDs</li><li>with longer use of NSAIDs</li></ul></li></ul> <b>Do not take NSAIDs, including diclofenac potassium for oral solution, right before or after a heart surgery called a "coronary artery bypass graft (CABG)."</b> <b>Avoid taking NSAIDs, including diclofenac potassium for oral solution, after a recent heart attack, unless your healthcare provider tells you to. You may have an increased risk of another heart attack if you take NSAIDs after a recent heart attack.</b> <ul style="list-style-type: none"><li>Increased risk of bleeding, ulcers, and tears (perforation) of the esophagus (tube leading from the mouth to the stomach), stomach and intestines:<ul style="list-style-type: none"><li>anytime during use</li><li>without warning symptoms</li><li>that may cause death</li></ul></li></ul> <b>The risk of getting an ulcer or bleeding increases with:</b> <ul style="list-style-type: none"><li>past history of stomach ulcers, or stomach or intestinal bleeding with use of NSAIDs</li><li>taking medicines called "corticosteroids", "anticoagulants", "SSRIs", or "SNRIs"</li><li>increasing doses of NSAIDs</li><li>longer use of NSAIDs</li><li>smoking</li><li>drinking alcohol</li><li>older age</li><li>poor health</li><li>advanced liver disease</li><li>bleeding problems</li></ul> <b>Diclofenac potassium for oral solution should only be used:</b> <ul style="list-style-type: none"><li>exactly as prescribed</li><li>at the lowest dose possible for your treatment</li><li>for the shortest time needed</li></ul> <b>What is diclofenac potassium for oral solution?</b> Diclofenac potassium for oral solution is a prescription medicine used to treat migraine attacks in adults. It does not prevent or lessen the number of migraines you have, and it is not for other types of headaches. Diclofenac potassium for oral solution contains diclofenac potassium (a non-steroidal anti-inflammatory drug or NSAID).
<b>How should I take diclofenac potassium for oral solution?</b> Take diclofenac potassium for oral solution exactly as your healthcare provider tells you to take it. Take 1 dose of diclofenac potassium for oral solution to treat your migraine headache: <ul style="list-style-type: none"><li>open packet only when you are ready to use it</li><li>empty contents of packet into 1 to 2 ounces (30 to 60 mL) of water</li><li>mix well and drink the water and powder mixture</li><li>throw away empty packet in a safe place and out of the reach of children.</li></ul> <ul style="list-style-type: none"><li>taking diclofenac potassium for oral solution with food may cause a reduction in effectiveness compared to taking diclofenac potassium for oral solution on an empty stomach</li></ul> <ul style="list-style-type: none"><li>do not take more diclofenac potassium for oral solution than directed by your healthcare provider. In case of overdose, get medical help or contact a Poison Control Center right away</li></ul>
<b>Who should not take diclofenac potassium for oral solution?</b> <b>Do not take diclofenac potassium for oral solution:</b> <ul style="list-style-type: none"><li>if you have had an asthma attack, hives, or other allergic reaction with aspirin, diclofenac, or any other NSAIDs.</li><li>right before or after heart bypass surgery.</li></ul>
<b>Before taking diclofenac potassium for oral solution, tell your healthcare provider about all of your medical conditions, including if you:</b> <ul style="list-style-type: none"><li>have liver or kidney problems</li><li>have a history of stomach ulcer or bleeding in your stomach or intestines</li><li>have any allergies to any medicines</li><li>have chest pain, shortness of breath, irregular heartbeats</li><li>have high blood pressure</li><li>have asthma</li><li>are pregnant, think you might be pregnant, or are trying to become pregnant. Taking NSAIDs, including diclofenac potassium for oral solution, at about 20 weeks of pregnancy or later may harm your unborn baby. If you need to take NSAIDs for more than 2 days when you are between 20 and 30 weeks of pregnancy, your healthcare provider may need to monitor the amount of fluid in your womb around your baby. <b>You should not take NSAIDs after about 30 weeks of pregnancy.</b></li><li>are breastfeeding or plan to breastfeed.</li><li>have a headache that is different from your usual migraine</li></ul>

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

Diclofenac potassium for oral solution has analgesic, anti-inflammatory, and antipyretic properties.

The mechanism of action of diclofenac potassium for oral solution, like that of other NSAIDs, is not completely understood but involves inhibition of cyclooxygenase (COX-1 and COX-2). Diclofenac is a potent inhibitor of prostaglandin synthesis *in vitro*. Diclofenac concentrations reached during therapy have produced *in vivo* effects. Prostaglandins sensitize afferent nerves and potentiate the action of bradykinin in inducing pain in animal models. Prostaglandins are mediators of inflammation. Because diclofenac is an inhibitor of prostaglandin synthesis, its mode of action may be due to a decrease of prostaglandins in peripheral tissues.

12.3 Pharmacokinetics

Absorption

Diclofenac is 100% absorbed after oral administration compared to intravenous administration as measured by urine recovery. However, due to first-pass metabolism, only about 50% of the absorbed dose is systemically available. In fasting volunteers, measurable plasma levels were observed within 5 minutes of dosing with diclofenac potassium for oral solution. Peak plasma levels were achieved at approximately 0.25 hour in fasting normal volunteers, with a range of 0.17 to 0.67 hours. High fat food had no significant effect on the extent of diclofenac absorption, but there was a reduction in peak plasma levels of approximately 70% after a high fat meal. Decreased C<sub>max</sub> may be associated to decreased effectiveness.

Distribution

The apparent volume of distribution (V/F) of diclofenac potassium is 1.3 L/kg.

Diclofenac is more than 99% bound to human serum proteins, primarily to albumin. Serum protein binding is constant over the concentration range (0.15 to 105 µg/mL) achieved with recommended doses.

Elimination

Five diclofenac metabolites have been identified in human plasma and urine. The metabolites include 4'-hydroxy-, 5-hydroxy-, 3'-hydroxy-, 4',5-dihydroxy- and 3'-hydroxy-4-methoxy diclofenac. The major diclofenac metabolite, 4'-hydroxydiclofenac, has very weak pharmacologic activity. The formation of 4'-hydroxy diclofenac is primarily mediated by CYP2C9. Both diclofenac and its oxidative metabolites undergo glucuronidation or sulfation followed by biliary excretion.

Acylglucuronidation mediated by UGT2B7 and oxidation mediated by CYP2C9 may also play a role in diclofenac metabolism. CYP3A4 is responsible for the formation of minor metabolites, 5-hydroxy and 3'-hydroxy- diclofenac. In patients with renal impairment, peak concentrations of metabolites 4'-hydroxy- and 5'-hydroxydiclofenac were approximately 50% and 4% of the parent compound after single oral dosing compared to 27% and 1% in normal healthy subjects.

Excretion

Diclofenac is eliminated through metabolism and subsequent urinary and biliary excretion of the glucuronide and the sulfate conjugates of the metabolites. Little or no free unchanged diclofenac is excreted in the urine. Approximately 65% of the dose is excreted in the urine and approximately 35% in the bile as conjugates of unchanged diclofenac plus metabolites. Because renal elimination is not a significant pathway of elimination for unchanged diclofenac, dosing adjustment in patients with mild to moderate renal dysfunction is not necessary. The terminal half-life of unchanged diclofenac is approximately 2 hours.

Specific Populations

**Race:** There are no pharmacokinetic differences due to race.

**Hepatic Impairment:** The liver metabolizes almost 100% of diclofenac; there is insufficient information available to support dosing recommendations for diclofenac potassium for oral solution in patients with hepatic insufficiency [see **Warnings and Precautions (5.3) and Use in Specific Populations (8.6)**].

**Renal Impairment:** In patients with renal impairment (mean clearance 60 to 90, 30 to 60, and <30 mL/min; N=6 in each group), AUC values and elimination rate were comparable to those in healthy subjects [see **Warnings and Precautions (5.6) and Use in Specific Populations (8.7)**].

Drug Interaction Studies

**Aspirin:** When NSAIDs were administered with aspirin, the protein binding of NSAIDs were reduced, although the clearance of free NSAID was not altered. The clinical significance of this interaction is not known. See Table 2 for clinically significant drug interactions of NSAIDs with aspirin [see **Drug Interactions (7)**].

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, and Impairment of Fertility

Carcinogenesis

Long term carcinogenicity studies in rats given diclofenac sodium up to 2 mg/kg/day (less than the recommended human dose [RHD] of 50 mg/kg/day on a body surface area [mg/m<sup>2</sup>] basis) have revealed no significant increases in tumor incidence. There was a slight increase in benign mammary fibroadenomas in mid-dose treated (0.5 mg/kg/day or 3 mg/m<sup>2</sup>/day) female rats at high-dose females had excessive mortality, but the increase was not significant for this common rat tumor. A 2-year carcinogenicity study conducted in mice revealed that diclofenac sodium at doses up to 0.3 mg/kg/day (less than the RHD on a mg/m<sup>2</sup> basis) in males and 1 m/kg/day (less than the RHD on a mg/m<sup>2</sup> basis) in females did not reveal any oncogenic potential.

Mutagenesis

Diclofenac sodium was not genotoxic *in vitro* (reverse mutation in bacteria [Ames], mouse lymphoma L5178Y, and *in vivo* [including dominant lethal and male germinal epithelial chromosomal aberration in Chinese hamster]) assays.

Impairment of Fertility

Diclofenac sodium administered to male and female rats at 4 mg/kg/day (less than the RHD on a mg/m<sup>2</sup> basis) did not affect fertility.

14 CLINICAL STUDIES

The efficacy of diclofenac potassium for oral solution in the acute treatment of migraine headache was demonstrated in two randomized, double-blind, placebo-controlled trials. Patients enrolled in these two trials were predominantly female (85%) and white (86%), with a mean age of 40 years (range: 18 to 65). Patients were instructed to treat a migraine of moderate to severe pain with 1 dose of study medication. Patients evaluated their headache pain 2 hours later. Associated symptoms of nausea, photophobia, and phonophobia were also evaluated. In addition, the proportion of patients who were "sustained pain free", defined as a reduction in headache severity from moderate or severe pain to no pain at 2 hours post-dose without a return of mild, moderate, or severe pain and no use of rescue medication for 24 hours post-dose, was also evaluated. In these studies, the percentage of patients achieving pain freedom 2 hours after treatment and sustained pain freedom from 2 to 24 hours post-dose was significantly greater in patients who received diclofenac potassium for oral solution compared with those who received placebo [see Table 3]. The percentage of patients achieving pain relief 2 hours after treatment (defined as a reduction in headache severity from moderate or severe pain to mild or no pain) was also significantly greater in patients who received diclofenac potassium for oral solution compared with those who received placebo [see Table 3].

Table 3: Percentage of Patients with 2-Hour Pain Freedom, Sustained Pain Freedom 2 to 24 Hours, and 2-Hour Pain Relief Following Treatment

Study 1	Diclofenac Potassium for Oral Solution (n=265)	Placebo (n=257)
2-Hour Pain Free	24%	13%
2 to 24h Sustained Pain Free	22%	10%
2-Hour Pain Relief	48%	27%
Study 2	Diclofenac Potassium for Oral Solution (n=343)	Placebo (n=347)
2-Hour Pain Free	25%	10%
2 to 24h Sustained Pain Free	19%	7%
2-Hour Pain Relief	65%	41%

The estimated probability of achieving migraine headache pain freedom within 2 hours following treatment with diclofenac potassium for oral solution is shown in Figure 1.

Figure 1: Percentage of Patients with Initial Headache Pain Freedom within 2 Hours

There was a decreased incidence of nausea, photophobia and phonophobia following administration of diclofenac potassium for oral solution, compared to placebo. The efficacy and safety of diclofenac potassium for oral solution was unaffected by age or gender of the patient.

16 HOW SUPPLIED/STORAGE AND HANDLING

Diclofenac Potassium for Oral Solution USP 50 mg, is a white to off-white, buffered, flavored powder for oral solution, supplied as individual dose packets. Each individual packet is designed to deliver a dose of 50 mg diclofenac potassium when mixed in water.

NDC 51672-4240-8 Individual Diclofenac Potassium for Oral Solution Packet

NDC 51672-4240-6 Carton of nine (9) Diclofenac Potassium for Oral Solution Packets

Storage

Store at 20° to 25°C (68° to 77°F) [see USP Controlled Room Temperature].

17 PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Medication Guide) that accompanies each prescription dispensed. Inform patients, families, or their caregivers of the following information before initiating therapy with diclofenac potassium for oral solution and periodically during the course of ongoing therapy.

Cardiovascular Thrombotic Events

Advise patients to be alert for the symptoms of cardiovascular thrombotic events, including chest pain, shortness of breath, weakness, or slurring of speech, and to report any of these symptoms to their healthcare provider immediately [see **Warnings and Precautions (5.1)**].

Gastrointestinal Bleeding, Ulceration, and Perforation

Diclofenac potassium for oral solution, like other NSAIDs, can cause GI discomfort and more serious GI adverse events such as ulcers and bleeding, which may result in hospitalization and even death. Inform patients of the increased risk, and advise patients to report symptoms of ulcerations and bleeding, including epigastric pain, dyspepsia, melena, and hematemesis to their healthcare provider. Inform patients of the importance of follow-up in the setting of concomitant use of low-dose aspirin for cardiac prophylaxis [see **Warnings and Precautions (5.2)**].

Hepatotoxicity

Inform patients of the warning signs and symptoms of hepatotoxicity (e.g., nausea, fatigue, lethargy, pruritus, diarrhea, jaundice, right upper quadrant tenderness, and "flu-like" symptoms). If these occur, instruct patients to stop taking diclofenac potassium for oral solution and seek immediate medical therapy [see **Warnings and Precautions (5.3)**].

Heart Failure and Edema

Advise patients to be alert for the symptoms of congestive heart failure including shortness of breath, unexplained weight gain, or edema and to contact their healthcare provider if such symptoms occur [see **Warnings and Precautions (5.5)**].

Anaphylactic Reactions

Inform patients of the signs of an anaphylactic reaction (e.g., difficulty breathing, swelling of the face or throat). Instruct patients to seek immediate emergency help if these occur [see **Contraindications (4) and Warnings and Precautions (5.7)**].

Serious Skin Reactions, Including DRESS

Advise patients to stop taking diclofenac potassium for oral solution immediately if they develop any type of rash, blisters, fever or other signs of hypersensitivity such as itching and to contact their healthcare provider as soon as possible. Diclofenac potassium for oral solution, like other NSAIDs, can cause serious skin reactions such as exfoliative dermatitis, Stevens-Johnson syndrome (SJS), toxic epidermal necrosis (TEN), and DRESS, which may result in hospitalizations and even death [see **Warnings and Precautions (5.5, 5.10)**].

Medication Overuse Headache

Inform patients that use of acute migraine drugs for 10 or more days per month may lead to an exacerbation of headache and encourage patients to record headache frequency and drug use (e.g., by keeping a headache diary) [see **Warnings and Precautions (5.11)**].

Fetal Toxicity

Inform pregnant women to avoid use of diclofenac potassium for oral solution and other NSAIDs starting at 30 weeks gestation because of the risk of the premature closing of the fetal ductus arteriosus. If treatment with diclofenac potassium for oral solution is needed for a pregnant woman between about 20 to 30 weeks gestation, advise her that she may need to be monitored for oligohydramnios. If treatment continues for longer than 48 hours [see **Warnings and Precautions (5.12) and Use in Specific Populations (8.1)**].

Lactation

Advise patients to notify their healthcare provider if they are breastfeeding or plan to breastfeed [see **Use in Specific Populations (8.2)**].

Female Fertility

Advise females of reproductive potential who desire pregnancy that NSAIDs, including diclofenac potassium for oral solution, may delay or prevent rupture of ovarian follicles, which has been associated with reversible infertility in some women [see **Use in Specific Populations (8.3)**].

Avoid Concomitant Use of NSAIDs

Inform patients that the concomitant use of diclofenac potassium for oral solution with other NSAIDs or salicylates (e.g., diflunisal, salsalate) is not recommended due to the increased risk of gastrointestinal toxicity, and little or no increase in efficacy [see **Warnings and Precautions (5.2) and Drug Interactions (7)**]. Alert patients that NSAIDs may be present in "over-the-counter" medications for treatment of colds, fever, or insomnia.
